

# FRAUDOLENT TRANSACTION CLASSIFICATION

RICCARDO LA MARCA, MATR. 1795030

BIG DATA COMPUTING COURSE A.A. 2021/2022

1

## **Introduction**

A brief presentation of the addressed problem

2

## **Dataset**

A brief description of the dataset used in the project

3

## **Explore and Feature Engineering**

How the dataset was modified

4

## **Machine Learning Models**

The ML models and Pipelines applied for the task

5

## **Results**

A description of the results obtained from the previous step

# OVERVIEW

## ADDRESSED PROBLEM

Financial fraud is a problem that has a huge impact on the financial industry

Credit card fraud detection is a challenge mainly due to 2 problems that it poses

- Both profiles of fraudulent and normal behaviours change
- Usually used datasets are highly skewed

The goal of the task is to create a Machine Learning model that, given a set of samples of fraudulent and not fraudulent transactions, is capable of classifying whether a new transaction is fraudulent or not.

## 2

## THE DATASET

The Dataset is available on [Kaggle](#)

### 3

## EXPLORE AND FEATURE ENGINEERING OUTLINE

## 3

## .1 - LABEL DISTRIBUTION

- With respect to the target label «isFraud» the dataset results **highly unbalanced**
- ~**96.5 %** are not-fraudulent transactions
- ~**3.5 %** are fraudulent transactions
- We have to handle this problem when splitting the dataset for training and testing the various ML models

## 3

## .2 – MISSING VALUES

- The dataset has a **high number** of features with a huge percentage **of missing values**
- The average range of percentages is **~70-90%**
- I handled this during the Feature Engineering step

### Features Dropping

- Drop features with percentage value of missing values greater or equal to 90%

### Standardization

- Standardize certain features
- Given different values for the same feature but with equal meaning, replace with a single more general value
- Take *yahoo.co.jp*, *yahoo.co.uk* and *yahoo.net*, I replace it with *yahoo*

### Imputing

- Use the imputer to replace null values in the dataset according to a specific strategy
- Discrete values use strategy *mean*
- Nulls in categorical values have been replaced with «N»

### Pearson Correlation

- Drop more features using the Pearson Correlation
- If the PC > .95, then drop that feature
- Avoiding duplicate features
